If we analyse all the parties involved in any construction work, we can categorise them into three main groups: the client, the contractor and the general public. The ideal situation is when all three parties are in agreement and satisfied with the successful outcome of the construction work. Problems arise when one of the parties becomes a victim of imbalance in this relationship. The conventional construction methods based upon principles that "more is paid for less efficient work" are no longer appropriate to present-day society. Universally acceptable construction methods must embody the Five Construction Principles.

Tubular sheet piles are tubular piles provided with an interlock, which gives them enormous cross-sectional strength and bending rigidity. Therefore, this type of pile is used widely in ports and rivers (for coastal walls, revetments and breakwaters), urban engineering projects (for retaining walls and cofferdams), bridges (for tubular sheet pile foundations), and many other applications. The Tubular Sheet Pile Press-in Method utilizes the superiority of the press-in principle to insert piles continuously, without causing any structural damage due to noise or vibration, resulting in a strong implant structure.

The tubular sheet pile press-in machine (Tubular Piler) uses a hydraulically-powered static load press-in method, so that piles can be installed precisely, while monitoring the bearing capacity of each individual pile and ensuring there is no damage to the pile or disturbance of the ground. This enables the safe construction of a high-quality continuous wall that can withstand both horizontal and vertical forces in any direction.

Furthermore, by using the “GRB system” so that all of the steps - transporting, pitching and pressing in the piles - are carried out from on top of the installed piles, rapid and compact construction is possible in any location, without the need for temporary structures. The result is a truly excellent balance of the Five Construction Principles “Environmental Protection, Safety, Speed, Economy and Aesthetics”.

Efficient Construction of Robust Continuous-Pile Walls Using Immensely Strong and Durable Tubular Sheet Piles

The tubular sheet pile is an enormously durable pile which is suited to port construction works, flood and tidal surge protection in river basins, anti-seismic strengthening of bridge pillars, bridge foundations (tubular sunken wells), and so on. It can be adapted to different design criteria by altering the pile diameter and thickness, thus enabling efficient and intelligent construction of many various structures for different purposes. The Tubular Piler is compatible with tubular sheet piles with diameters from 500-1,500, and its noise-free and vibration-free process, with no risk of overturning, makes for a safe construction project that is respectful of the environment.

Features of Tubular Sheet Pile Press-in Method

- Creates a Highly Rigid Wall Structure
- Respectful of the Surrounding Area
- Reduces Construction Costs
- Excellent Safety With No Risk of Overturning

Construction works can be carried out with Environmentally-friendly considerations, lower cost and shorter work duration at any work conditions.
GRB System for "Temporary Work Less" Construction

The GRB system applies the Press-in Principle which states that a reaction force is obtained from completed piles. In this way, all of the steps of the process, from transporting and pitching the pile, to pressing it in, can be carried out from a position on top of the existing piles. And since all of the equipment is self-supporting and grips onto the completed piles, there is no risk of overturning, and the area affected by the works is restricted to the width of the machinery on the piles. Even over water, on sloping or uneven ground, in narrow spaces, or locations with restricted headroom, the GRB system has no need for any temporary structures, like platforms or roadways, and can focus efficiently on the purpose of the project - building the main structure.

Standard Components of GRB system

Without using any temporary structures, a revetment is built with an implant structure of piles that are united with the Earth.

During Press-in Work

After Completion of Press-in Work
Applications & Reference

Sunken Well Foundations Using Tubular Sheet Piles

The Tubular Piler grips completed piles and moves by itself along the top of the piles while progressing with the press-in work. This minimizes the requirements for heavy equipment and temporary staging, even in bridge support and sunken well foundation projects, resulting in lower costs and faster completion.

Coastal / Riverbank Protection

Since there is no need for temporary works and only compact machinery and equipment are required, then the area affected by the project is minimized and the traffic on the river and the bridge is not disturbed at all.

Reference

Bridge Improvement Project No. 1, Naka River between Mito and Hitachi-Aoyagi Ibaragi Prefecture

1000-dia. tubular sheet piles pressed into hard ground (mudstone layer, STP-N value: 150). No requirement for temporary pier and no disturbance to nearby railway.

Reference

Shingashi River Renovation Work Tokyo

With the GRB system, there were no temporary facilities, and work could focus efficiently on building the river revetments. Work completed without affecting traffic, even in sections with restricted headroom.
## Retaining Walls for Highways

**Tubular Sheet Pile Press-in Method**

Because the Tubular Piler grips onto installed piles and moves along the top of the piles as the work progresses, it can operate without needing any platform for heavy machinery, even when working on a slope. Using the GRB system also means that the affected area is kept to a minimum, and adjacent activities are not disrupted.

**Conventional Method**

Despite working alongside a very busy highway, the project was completed without the need for temporary works or banking, and without disrupting normal activities. The mechanism grips tightly onto completed piles, which means that the work procedure is safe, with no risk of toppling.

### Reference

**Shinsakura-ga-oka Interchange Widening**

Kanagawa Prefecture

Using the Tubular Clear Piler which is especially designed for working with low headroom by the Overhead Clearance Method, piles could be installed efficiently without disturbing other activities, even when the height was restricted to just 2.37 m.

### Reference

**Kuramae Bridge Antiseismic Strengthening and Repair Project**

Tokyo

When headroom is restricted, for instance, under a bridge, our compact machinery, plus the principle of gripping the completed piles near the top of the pile, means that the available height can be used to the maximum and work can be completed without needing to remove overhead obstructions. Where height restrictions are especially strict, an excellent option is the Tubular Clear Piler, in which the machine dimensions are compressed to the very minimum.

## Reinforcement of Bridge Pillar Foundations

### Tubular Sheet Pile Press-in Method

**Conventional Method**

Because the Tubular Piler grips onto installed piles and moves along the top of the piles as the work progresses, it can operate without needing any platform for heavy machinery, even when working on a slope. Using the GRB system also means that the affected area is kept to a minimum, and adjacent activities are not disrupted.

### Reference

**Kuramae Bridge Antiseismic Strengthening and Repair Project**

Tokyo

Using the Tubular Clear Piler which is especially designed for working with low headroom by the Overhead Clearance Method, piles could be installed efficiently without disturbing other activities, even when the height was restricted to just 2.37 m.

### Auxiliary Equipment

**Tubular Clamp Crane**

- **CB3-2**
  - Crane Power: 10.0 ton × 6.5 m
  - Max. Working Radius: 20.0 m
  - Mass: 18800 kg

- **CB4-1**
  - Crane Power: 20.0 ton × 7.0 m
  - Max. Working Radius: 34.0 m
  - Mass: 46300 kg

### Pile Runner (For Tubular Sheet Piles and Tubular Piles)**

- **PR217**
  - Carrying Capacity: 15.0 t
  - Compatible Piles: Tubular Sheet Pile Ø 700-1200
  - Transporting Rails: N/A
  - Total Mass: 8900 kg

- **TB4**
  - Carrying Capacity: 5.0 t
  - Compatible Piles: Tubular Sheet Pile Ø 800-1500
  - Transporting Rails: Type 3, U Sheet Pile
  - Total Mass: 850 kg

*Product specifications may be changed without prior notice.*
### Standard Press-in Procedure

#### Initial Press-in

1. **Press-in Sheet Piles as Reaction Piles**
2. **Install Reaction Stand**
3. **Assemble the three parts of the main body**
4. **Press-in from Reaction Stand**

#### Standard Installation

1. **Pitch the pile and grip with Chuck**
2. **Check verticality and alignment, and then start press-in work**
3. **Press in pile (A) until bearing capacity is achieved**
4. **Open clamp and start self-moving**
5. **Close clamp and end self-moving**
6. **Press in pile (A) to datum level**

### Cross-Sectional Performance Compared with Other Pile Types

The table below shows typical models of the four main types of pile, distributed by section performance and pile weight. The tubular sheet pile clearly has much higher cross-sectional performance than U and Z sheet piles. Also, when compared with H sheet piles which give similar high cross-sectional performance, the tubular sheet pile involves virtually no increase in pile weight, and therefore is preferable in economic terms.

**Corner Installation**

The PP150, PP200, PP260, PP300 and PP400 can install tubular sheet piles in the positions 1 and 2 shown left. The CLP 200 is not capable of corner installation, and requires a special approach.

* For details, please contact the Japan Press-in Association.

**Curve Installation**

**Installation Properties**

**Tubular Sheet Pile Press-in Method**

**Eco-Friendly Design**

**Exhaust Gas Cleaning Compliant with "Offroad" Law**

The new Power Unit is equipped with a new-generation environmentally friendly engine. The high combustion efficiency, allied with Giken’s independent hydraulic control technology, means that exhaust gases are cleaned thoroughly and effectively, and the equipment complies with the “Offroad” Law regulating work vehicle emissions and Level 3 of the Ministry of Land, Infrastructure, Transport and Tourism’s exhaust gas measures for construction machinery.

**Biodegradable Oils for Standard Specification**

The press-in machinery uses special biodegradable hydraulic oil (Piler Eco Oil) and grease (Piler Eco Grease) developed by Giken in collaboration with oil manufacturers. In the event of any escape into the water or soil, the oil and grease is decomposed by natural bacteria and has no effect on the ecosystem.

**Meeting Ultra-Low-Noise Standards**

The Power Unit also meets the “ultra-low-noise standards” set by the MLIT.

* These figures indicate theoretical limits and suitable margins should be allowed when designing actual projects. These figures are applicable to the use of standard tubular sheet piles.
### Work Management

#### Automatic Press-in Operation System

With the Press-in Method, a down-stroke/up-stroke action is applied to the pile being pressed-in in order to eliminate any elements which act to obstruct the penetration of the pile (elements which obstruct the execution of press-in work), so as to achieve a structure of excellent quality after completion. The press-in stroke and extraction stroke, and the maximum press-in force used, etc. are set to optimal values depending on the ground conditions, the pile length, and the construction conditions, and so on. With the Automatic Press-in Operation System, these set conditions are input into the press-in machine and the most efficient press-in operation possible is executed faithfully. Implementing the Automatic Press-in Operation System means that press-in work can proceed in a logical, scientific manner. The charts below show press-in data for manual operation and automatic operation, at the same site.

**Press-in Record by Manual Operation**

**Press-in Record by Automatic Operation**

![Graphs showing press-in data for manual and automatic operations.]

The Power Unit is connected to a PC and the state of press-in work is captured in real time.

#### Press-in Quality Control System

**Scientific analysis of the state of press-in work, using Press-in Monitoring Data for each pile**

Data about the press-in work, such as the press-in force and press-in speed, is measured and collected in real time, enabling scientific management of the state of the work. By linking this data to a borehole diagram, it is possible to make reliable decisions about optimal press-in work settings for different types of ground, and countermeasures for obstacles, etc.

### EMOS Eco Monitoring System

**Monitoring the behaviour of the machinery during construction and the accomplishment of reliable safety within regulatory standards**

**EMOS**: The Eco Monitoring System (EMOS) is an immensely flexible environmental monitoring set-up with all the necessary measuring equipment mounted in a single custom-designed vehicle. The technical data provided by EMOS gives a scientific demonstration of the superiority of the construction method and the safety and reliability of the procedure, which can be shown to clients, local residents and other interested parties.

**Environmental Factors Monitored by EMOS**

- Safety (Automatic Control of Machinery)
- Ground Displacement
- Settlement
- Slope
- Noise
- Vibration
- Weather

**Construction machinery stopped automatically by image data processing (Systematic Control of Safety)**

EMOS uses camera monitoring equipment and image processing to automatically control the operations of the construction machines, so that work is carried out within the established safe area. This safety control system enables fast and cost-effective work that makes maximum use of the space inside the clearance limits, while ensuring excellent safety with regard to nearby structures, cables, and railway and road traffic.

- A warning level and stop level can be set in each of four areas.
- A warning or automatic stop is implemented, depending on the effect on existing structures.
- An image is recorded on the management computer whenever there is an abnormality in the warning and stop level detection.

**EMOS Eco Monitoring System**

**Construction Revolution**
THE FIVE CONSTRUCTION PRINCIPLES

Environmental Protection
Construction work should be environmentally friendly and free from pollution.

Safety
Construction work has to be carried out in safety and comfort with a method implementing the highest safety criteria.

Speed
Construction work should be completed in the shortest possible period of time.

Economy
Construction work must be done rationally with an inventive mind to overcome all constraints at the lowest cost.

Aesthetics
Construction work must proceed smoothly and the finished product should portray cultural and artistic flavour.

If we analyse all the parties involved in any construction work, we can categorise them into three main groups: the client, the contractor and the general public. The ideal situation is when all three parties are in agreement and satisfied with the successful outcome of the construction work. Problems arise when one of the parties becomes a victim of imbalance in this relationship. The conventional construction methods based upon principles that "more is paid for less efficient work" are no longer appropriate to present-day society. Universally acceptable construction methods must embody the Five Construction Principles.
